

Robust Options Valuation and Risk Management Workflows with Vola Dynamics Analytics

Misha Fomytskyi
Vola Dynamics
2021-10-28

Option valuation framework

- Discount rates
 - OMMs do not use the curve from your fixed income team
 - Can be name specific
- Dividends
 - Cash/proportional/continuous -> valuation for American options, risk of European
 - Dividend model: what's the definition of volatility with cash dividends?
- Borrow
 - Market value changes intraday
 - Asynchronicity and varying liquidity make implication complicated
- Volatility curves
 - Bias-free, arb-free, stable, easy to define dynamic properties
- Volatility time
 - Affects early exercise, parameter term structure, and vol interpolation

Option valuation

What is the fair value of an option?

- Cost of replication
 - My rates, taxes etc
 - Gives the expected cost of holding a hedged position
- Equilibrium of supply and demand
 - Market implied rates, borrows, dividends etc
 - Fair value means the probability of execution of a bid or an offer is the same at this price level
 - Can use to determine where to place orders or estimate portfolio liquidation value

Should I use my rates or the market rates to price options?

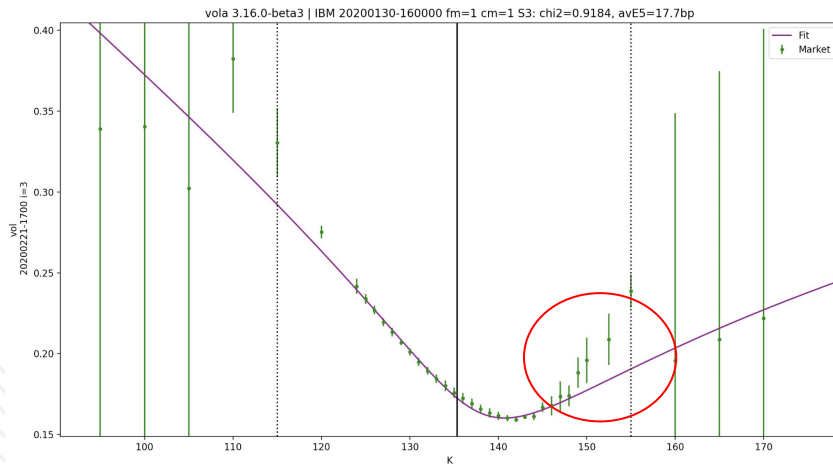

Option valuation: describing the option prices

- What information can be extracted from listed option prices?
 - Discount rates
 - Borrow curves
 - Dividend amounts, dividend model
 - Volatility time
 - Events
 - Volatility surface (equivalent to the implied probability density)
- What happens if you disagree with the market?
- How can you tell what's wrong and how to match the parameters that OMMs use in their valuations?

Example: incorrect curve type

Bad fit!

- $\chi^2 > 1$
- Crossings/bias in OTM options

Note the bias in
in-the-money options
in Dec 22 and Dec 23!

Example: discount rates (NDX)

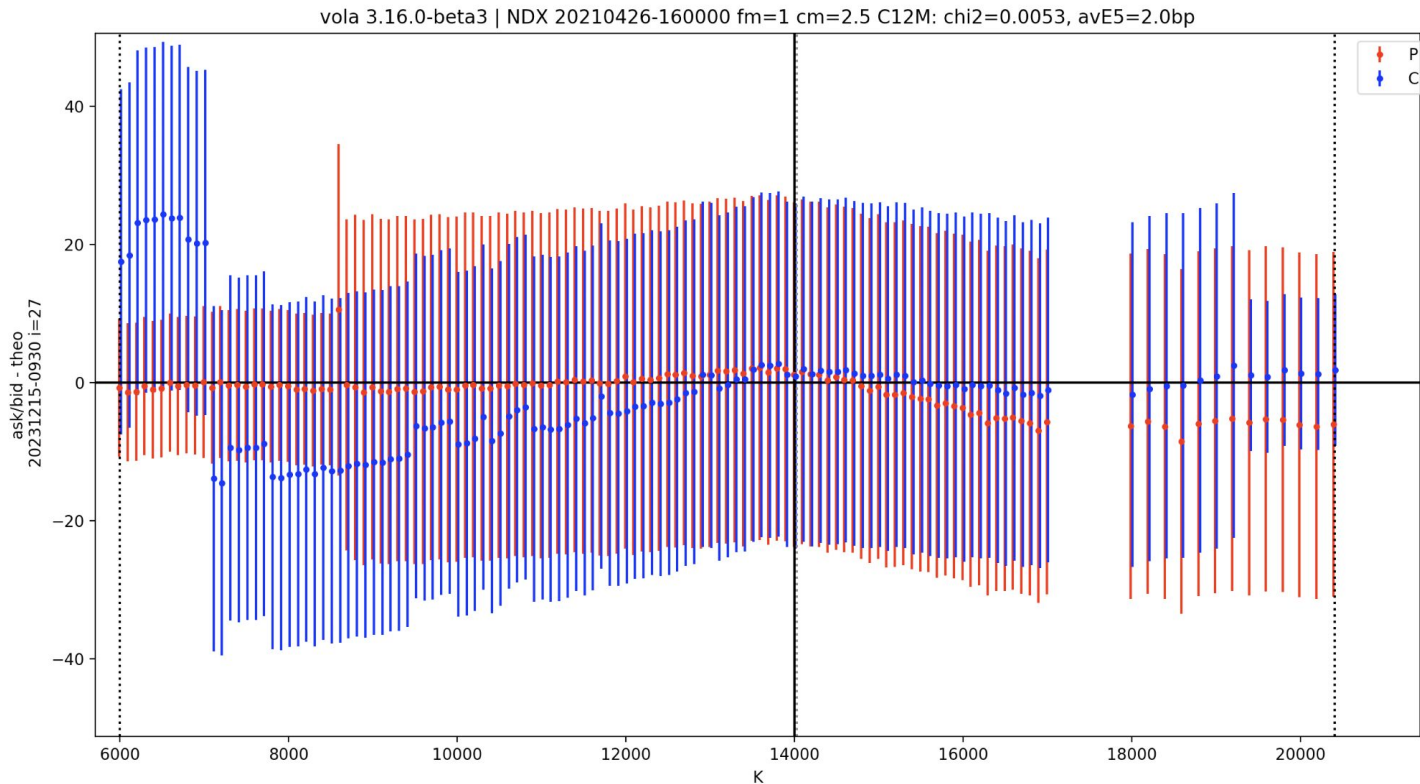

Graph shows the market bid/ask minus fitted theos (calls are blue, puts are red)... we see large fitting errors for ITM options

NDX is fit with discount rates implied from SPX options.

Such bias in long-dated options is typical for wrong discount rates.

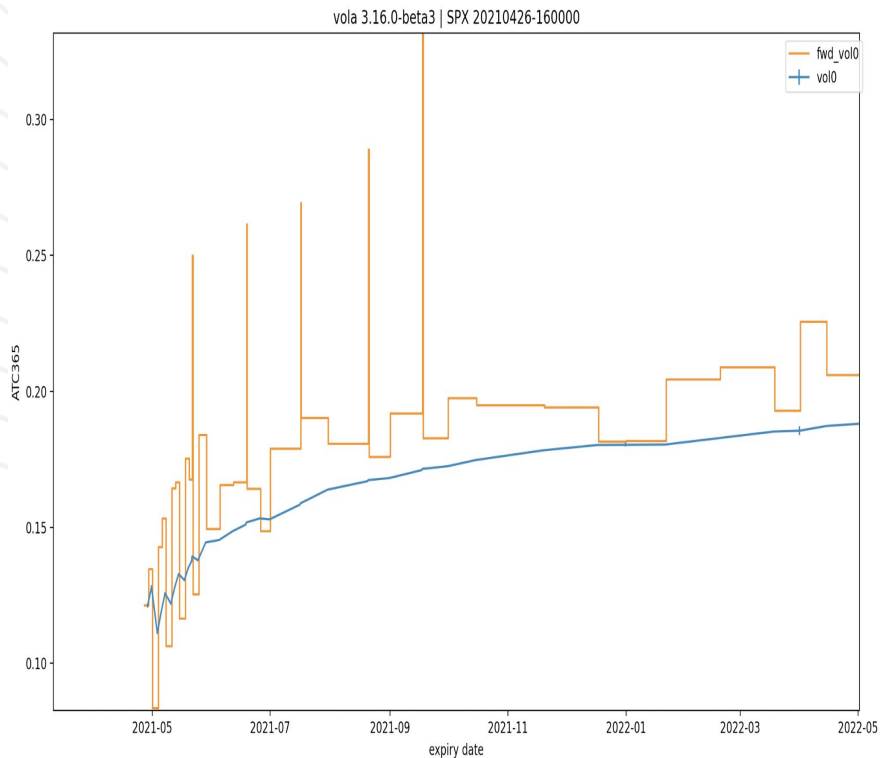

Example: discount rates (NDX)

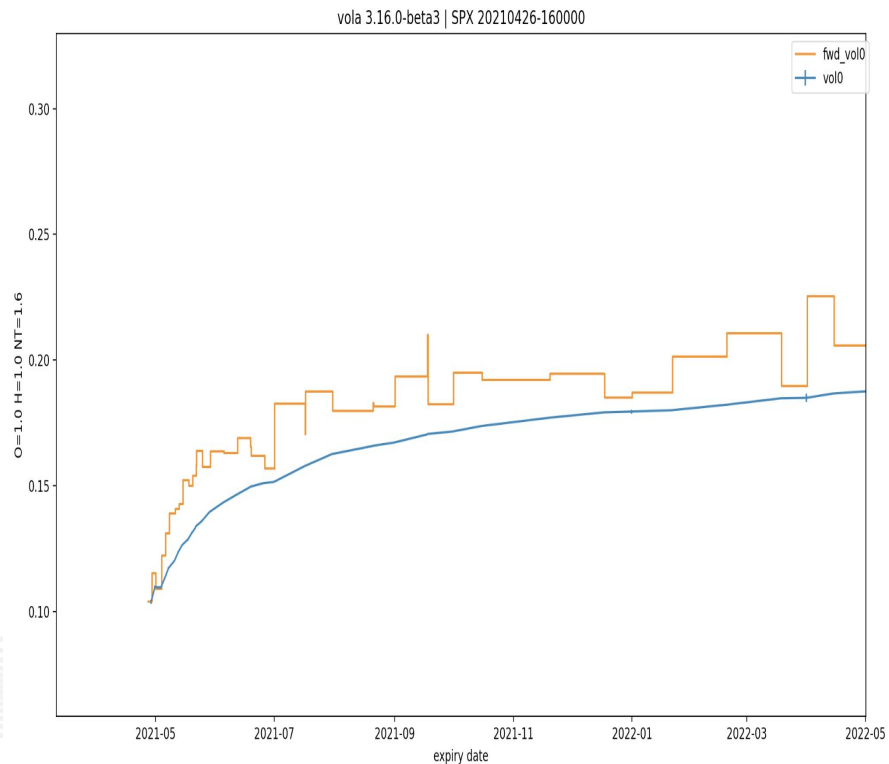

Discount rate
changed from 78bps
to 92bps mostly
removes the bias and
make all valuations
within BBO.

Volatility time and term structure of forward starting SPX vol

Clock time

Calibrated volatility time

Time converter: time in years between two datetimes

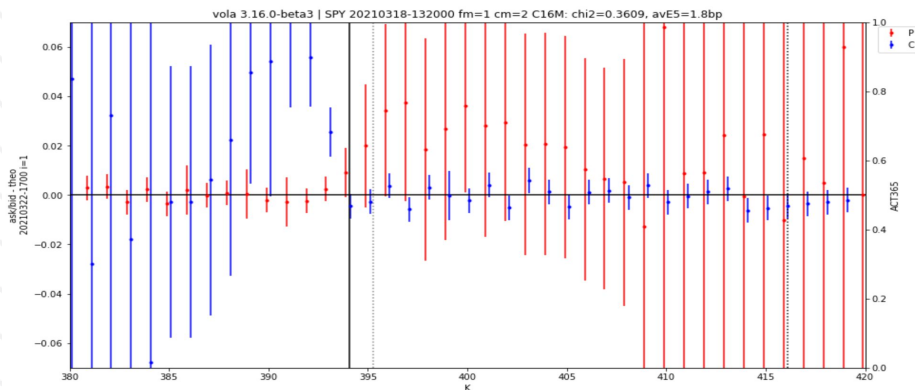

In volatility time variance accrues at different rates

- Intraday
- Overnight
- Non-trading

Volatility time affects SPY early exercise premium

Clock time

Calibrated vol time

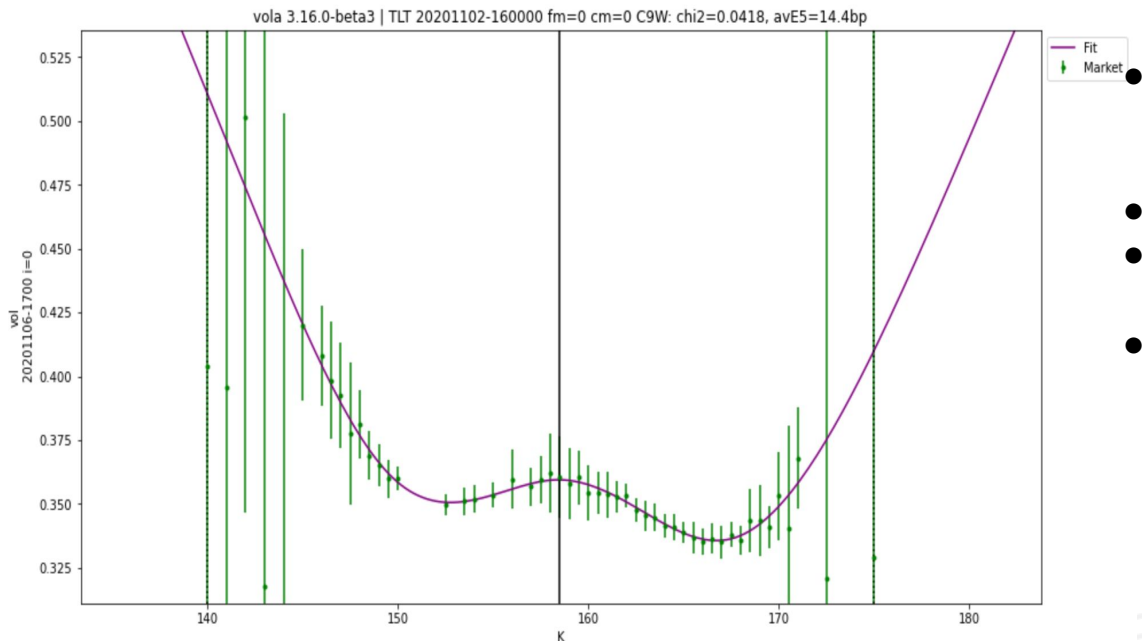

- SPY goes ex-div on Friday, hence need to early exercise calls on Thursday night to get the div
- Early exercise premium depends on how much variance accrues from Thursday afternoon to the close.
- Simple clock time does not take into account that variance accrues faster during trading hours, therefore, ITM calls are underpriced

Crypto vol fit example: SVI cannot fit BTC

Example: events, TLT before the US elections

- Negative curvatures first appeared ~2005 in tech (GOOG) & autos (GM, F)
- Cannot fit with SABR, SVI, SSVI
- Now present in nearly every geography and asset class
- Markets which relied on vols sampled at 5 deltas will likely need to adopt equity framework to describe event-driven return distributions

Summary

- Options fitting is a complex engineering problem
- Key ingredients:
 - Fast option pricer with cash dividends
 - Flexible yet sensible vol curves that can match any market including event
 - Robust vol fitter
 - Vol dynamics
- Valuations depend on many parameters from dividends and rates to time convention
- With robust infrastructure (such as provided by Vola Dynamics) thousands of underliers can be reliably fit with small teams.
